

CS 394B Introduction

Marco Canini

Cryptography Hash Functions I

- Take message m of arbitrary length and produces fixed-size (short) number $H(m)$
- **One-way function**
 - **Efficient:** Easy to compute $H(m)$
 - **Hiding property:** Hard to find an m , given $H(m)$
 - Assumes “ m ” has sufficient entropy, not just {“heads”, “tails”}
 - **Random:** Often assumes for output to “look” random

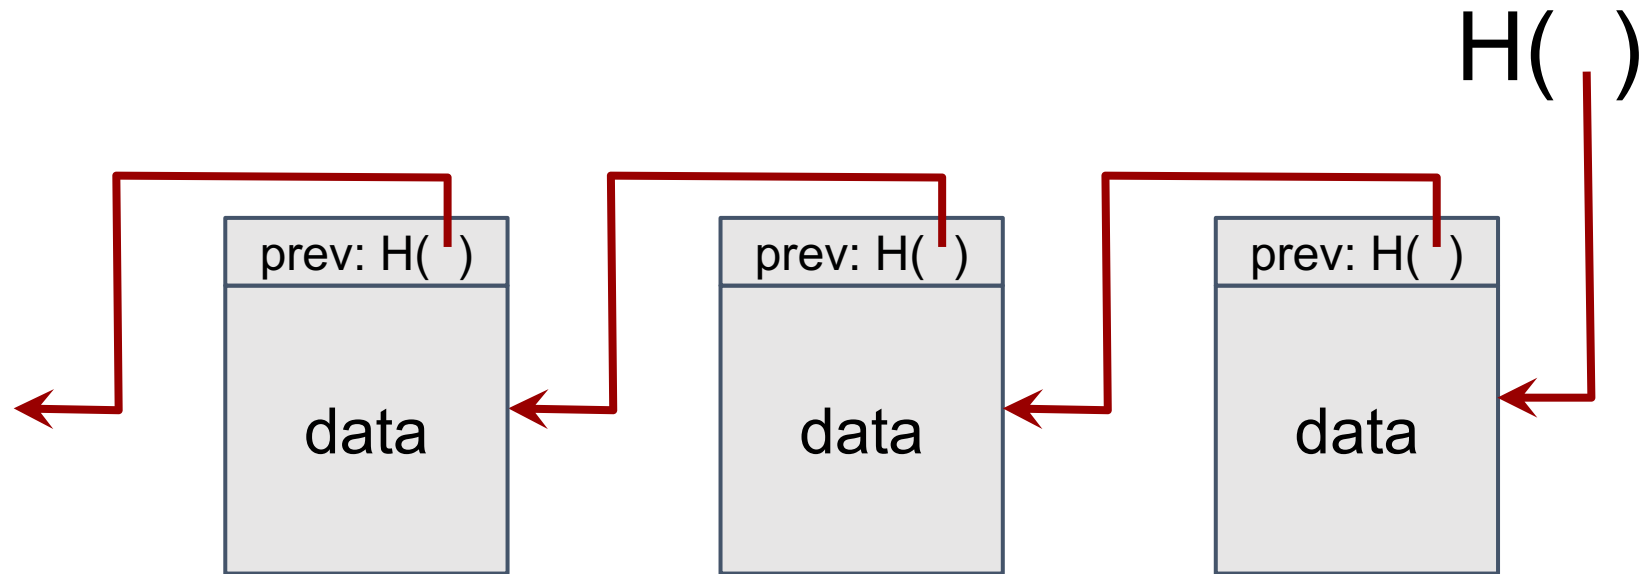

Cryptography Hash Functions II

- Collisions exist: $| \text{possible inputs} | \gg | \text{possible outputs} |$
... but hard to find
- Collision resistance:
 - Strong resistance: Find any $m \neq m'$ such that $H(m) == H(m')$
 - Weak resistance: Given m , find m' such that $H(m) == H(m')$
 - For 160-bit hash (SHA-1)
 - Finding any collision is birthday paradox: $2^{\{160/2\}} = 2^{80}$
 - Finding specific collision requires 2^{160}

Hash Pointers

Hash chains

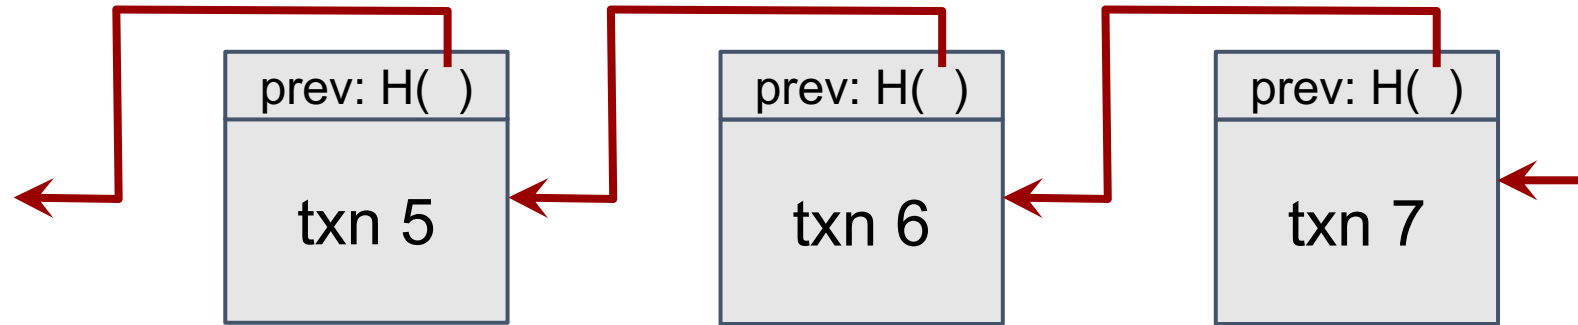

Creates a “tamper-evident” log of data

Hash chains

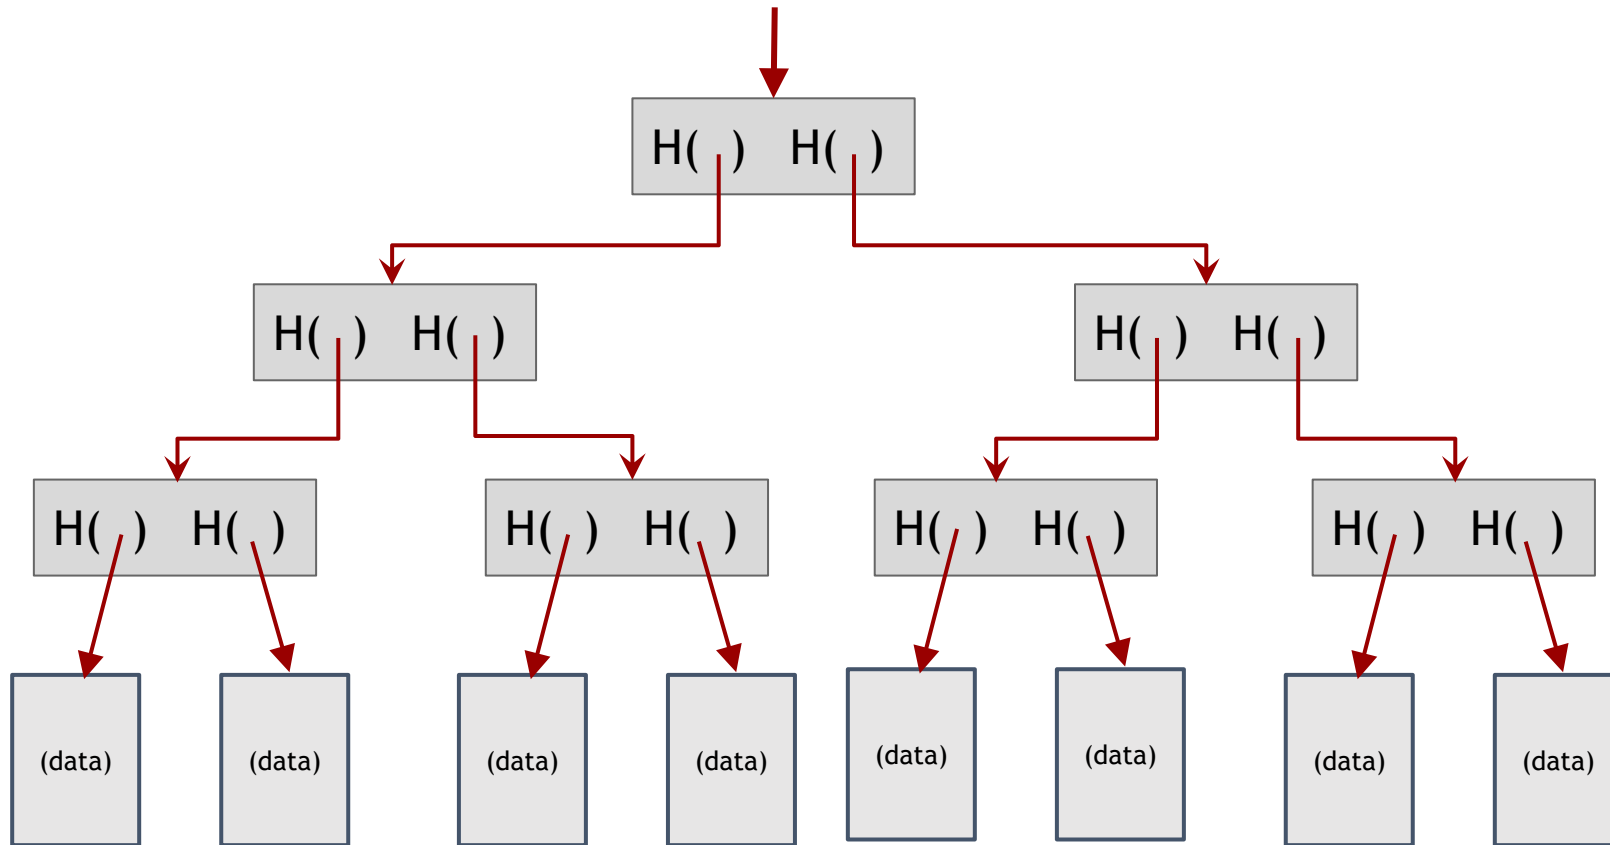

If data changes, all subsequent hash pointers change
Otherwise, found a hash collision!

Blockchain: Append-only hash chain

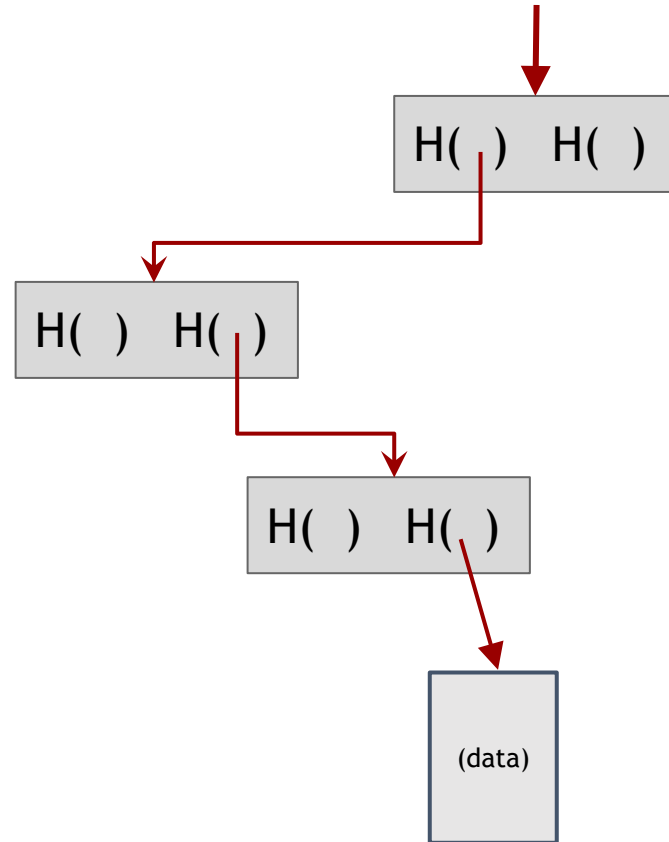

- Hash chain creates “tamper-evident” log of txns
- Security based on collision-resistance of hash function
 - Given m and $h = \text{hash}(m)$, difficult to find m' such that $h = \text{hash}(m')$ and $m \neq m'$

Merkle tree

Binary tree with hash pointers

proving membership in a Merkle tree

show $O(\log n)$ items

What we want from signatures

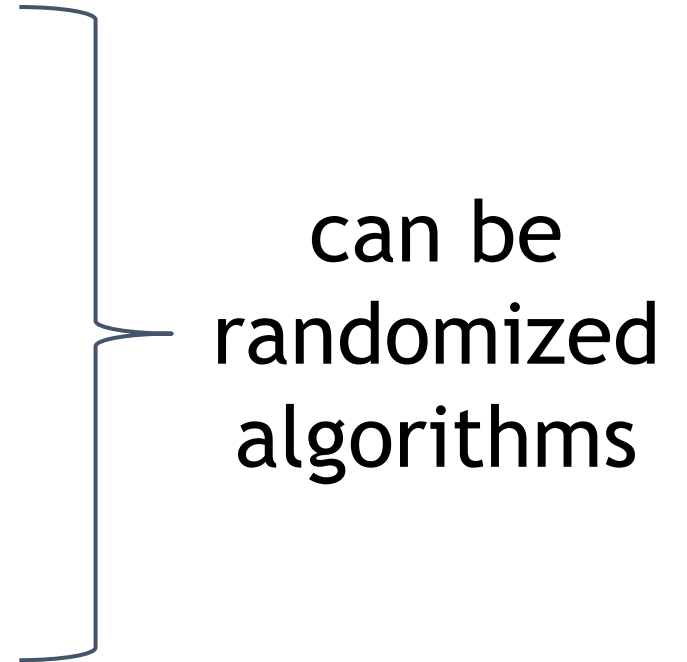

Only you can sign, but anyone can verify

Signature is tied to a particular document

can't be cut-and-pasted to another doc

API for digital signatures

- $(sk, pk) := \text{generateKeys}(\text{keysize})$
sk: secret signing key
pk: public verification key
- $\text{sig} := \text{sign}(sk, \text{message})$
- $\text{isValid} := \text{verify}(pk, \text{message}, \text{sig})$

can be
randomized
algorithms

Requirements for signatures

“valid signatures verify”

$\text{verify}(\text{pk}, \text{message}, \text{sign}(\text{sk}, \text{message})) == \text{true}$

“can’t forge signatures”

adversary who:

knows pk

gets to see signatures on messages of his choice

can’t produce a verifiable signature on another message

Useful trick: public key == an identity

if you see sig such that $verify(pk, msg, sig) == true$,
think of it as

pk says, “[msg]”.

to “speak for” pk , you must know matching secret key sk
